# Common Statistical Tests

Comparing Proportions  
of Two Groups

2

---

---

---

---

---

---

---

---

---

# Outline

- Comparing two groups with dichotomous outcomes
- 2 x 2 tables
- Summarizing information in 2 x 2 tables
- Chi-squared ( $\chi^2$ ) statistic
- Short-cut formula for  $\chi^2$  statistic for 2 x 2 tables

3

---

---

---

---

---

---

---

---

## Comparing Two Groups

- We are interested in whether 2 groups are the same with respect to some dichotomous characteristic or outcome.
- Data may be displayed in a 2 x 2 table

4

---

---

---

---

---

---

---

---

## 2 x 2 Tables

Treatment	Response to treatment		Total
	Yes	No	
A	37	13	50
B	17	53	70
Total	54	66	120

5

---

---

---

---

---

---

---

---

## Summarizing Information

Treatment	Response to treatment		Total	Proportion Responding
	Yes	No		
A	37	13	50	$37/50=0.74$
B	17	53	70	$17/70=0.24$
Total	54	66	120	$54/120=0.45$

6

---

---

---

---

---

---

---

---

## Summarizing Information

- 74% respond to Treatment A
- 24% respond to Treatment B
- There is a 50% absolute difference in response rate between Treatments A and B
- The relative difference in response rate between Treatments A and B is a 208% relative increase
- $(0.74-0.24)/0.24 = 2.08 \times 100 = 208\%$

7

---

---

---

---

---

---

---

---

## Summarizing Information

- The odds of responding to Treatment A:  
 $P(\text{responding})/P(\text{not responding}) = (37/50) / (13/50) = 2.85$
- The odds of responding to Treatment B:  
 $P(\text{responding})/P(\text{not responding}) = (17/70) / (53/70) = 0.32$
- The odds ratio of response (comparing Treatment A to Treatment B):  
 $(\text{odds in A}) / (\text{odds in B}) = 2.85 / 0.32 = 8.9$

8

---

---

---

---

---

---

---

---

## Comparing Two Groups

- Is the difference in response rates between the two treatments bigger than what we would expect due to chance alone?

9

---

---

---

---

---

---

---

---

## Comparing Two Groups

- What frequencies would we expect if response was the same by treatment?

Treatment	Response to treatment		Total
	Yes	No	
A			50
B			70
Total	54	66	120

10

---

---

---

---

---

---

---

---

---

---

## Comparing Two Groups

- What frequencies would we expect if response was the same by treatment?

Treatment	Response to treatment		Total
	Yes	No	
A	$0.45(50)=22.5$		50
B	$0.45(70)=31.5$		70
Total	54	66	120

11

---

---

---

---

---

---

---

---

---

---

## Comparing Two Groups

- What frequencies would we expect if response was the same by treatment?

Treatment	Response to treatment		Total
	Yes	No	
A	22.5	27.5	50
B	31.5	38.5	70
Total	54	66	120

12

---

---

---

---

---

---

---

---

---

---

## Observed vs Expected Counts

- Observed counts
- Expected counts

Treatment	Response to treatment		Total
	Yes	No	
A	37	13	50
B	17	53	70
Total	54	66	120

Treatment	Response to treatment		Total
	Yes	No	
A	22.5	27.5	50
B	31.5	38.5	70
Total	54	66	120

13

---

---

---

---

---

---

---

---

---

---

## Chi-Squared Statistic

- $\chi^2$  test statistic
  - Compares observed to expected counts across all k cells of a contingency table
  - Calculations use frequencies (counts) not proportions

$$\chi^2 = \sum_{i=1}^k \left[ \frac{(O_i - E_i)^2}{E_i} \right]$$

14

---

---

---

---

---

---

---

---

---

---

## Chi-Squared Statistic

- $\chi^2$  test statistic
  - Useful as a test of independence (no association; homogenous)
  - Test  $H_0$  that the samples are drawn from populations that are homogenous
- $\chi^2$  test statistic follows a  $\chi^2$  distribution
  - family of distributions
  - its shape depends on its degrees of freedom

15

---

---

---

---

---

---

---

---

---

---

## Chi-Squared Statistic

- $\chi^2$  test statistic

$$\chi^2 = \sum_{i=1}^k \left[ \frac{(O_i - E_i)^2}{E_i} \right]$$

$$\chi^2 = \frac{(37-22.5)^2}{22.5} + \frac{(13-27.5)^2}{27.5} + \frac{(17-31.5)^2}{31.5} + \frac{(53-38.5)^2}{38.5}$$

$$\chi^2 = 29.1 \text{ with 1 df}$$

16

---

---

---

---

---

---

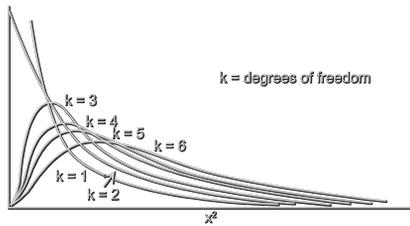

---

---

---

---

## $\chi^2$ Distributions

17

---

---

---

---

---

---

---

---

---

---

## Chi-Squared Statistic

- Short-cut formula for 2 x 2 table

Treatment	Response to treatment		Total
	Yes	No	
A	37=a	13=b	50=a+b
B	17=c	53=d	70=c+d
Total	54=a+c	66=b+d	120=n

$$\chi^2 = \frac{n(ad-bc)^2}{(a+c)(b+d)(a+b)(c+d)}$$

18

---

---

---

---

---

---

---

---

---

---

## Chi-Squared Statistic

- Short-cut formula for 2 x 2 table

Treatment	Response to treatment		Total
	Yes	No	
A	37=a	13=b	50=a+b
B	17=c	53=d	70=c+d
Total	54=a+c	66=b+d	120=n

19

---

---

---

---

---

---

---

---

## Chi-Squared Statistic

- Short-cut formula for 2 x 2 table

$$\chi^2 = \frac{n(ad-bc)^2}{(a+c)(b+d)(a+b)(c+d)}$$

$$\chi^2 = \frac{120(37(53)-13(17))^2}{(54)(66)(50)(70)}$$

$$\chi^2 = 29.1 \text{ with 1 df}$$

20

---

---

---

---

---

---

---

---

## Other Methods for 2 x 2 Tables

- Z test of difference in proportions between 2 groups
- Fisher's exact test
- Confidence interval for the true difference in proportions between 2 groups
- Odds ratio and confidence interval
- Mantel-Haenszel statistic for combining results from multiple 2 x 2 tables

21

---

---

---

---

---

---

---

---

## Summary

- Summarizing information in 2 x 2 tables
- Testing for differences between 2 groups
  - Are the groups “homogeneous” with respect to some characteristic?
  - Is there an association between group and characteristic?
  - Are group and the characteristic independent?

---

---

---
